

National Vaccination Coverage Estimates of Adolescents Aged 13-17 years by Selected Demographic and Access to Healthcare Characteristics Using National Immunization Survey – Teen (NIS-Teen), 2020 Public User Files (PUF).

Name: Xuan Gao

ID: 002666237

I. Introduction.

National Vaccination Coverage Estimates of Adolescents Aged 13-17 years by Selected Demographic and Access to Healthcare Characteristics Using National Immunization Survey is conducted by National Center for Immunization and Respiratory Diseases (NCIRD) and the National Center for Health Statistics (NCHS) of CDC.

The target population for the NIS-Teen is non-institutionalized adolescents aged 13–17 years living in United States households at the time of the interview. For the 2020 NIS-Teen, household interviews began on January 9, 2020 and ended on January 15, 2021. Provider data collection extended from February 2020 through April 2021.

The official coverage estimates reported from the NIS-Teen are proportions of adolescents up-to-date with respect to the recommended numbers of doses of all routinely recommended vaccines for adolescents and selected catch-up vaccines (Robinson et al. 2020).

The data I would use to estimate coverage is coded **P_UTDHPV_15INT** which indicates teens that either have received 3 or more HPV doses or have received 2 or more HPV doses with the 1st dose before age 15 years and at least 5 months minus 4 days between the 1st and 2nd doses.

Methods.

Study Cohort:

- Inclusion criteria:
All adolescents aged 13-17 years with adequate provider data (ADP) in the NIS-Teen 2020 PUF.
- Exclusion criteria:
Adolescents in the U.S. Territories (i.e., Guam, Puerto Rico, and U.S. Virgin Islands.)
- The provider-phase sampling weight variable for producing estimates for teens with adequate provider data in the United States excluding territories is coded **PROVWT_C**.
- Total sample size should be equal to **20,163**.

II. Results: Part I

In this survey, total 20,163 samples collected.

13-15 years old group were weighted 60.5% (N=12,447) and 16-17 years old group accounts for weighted 39.5% (N= 7716). Male group were weighted 51%(N=12,447) and female accounts for weighted 49%(N=9576). The census region which includes northeast, Midwest, south and west 's proportion is 15.8%, 21.1%, 39%, 24.2% respectively. For the, mother's Educational Level, about half of them are college graduated. Non-Hispanic White accounts for the biggest part among all races. About half of the candidates' mother education level is above college graduate.

The sample sizes and weighted% for each variable is presented in the below table.

TABLE 1. Sample Characteristics of Adolescents Aged 13-17 Years in the United States, by Selected Demographic and Access-To-Care Variables--NIS-Teen 2020

Characteristic		Overall	
		Sample Size	Weighted %

	All STD/school/teen clinics or other facilities	505	2.3
	Mixed ^{††}	3356	14.3
	Unknown/Don't Know ^{††}	2059	13.5

* Reference level.

[§]Insurance categories are mutually exclusive.

^{||} Includes IHS, military, CHIP, and some private.

** Status of health-care visit at age 11-12 years based on provider reported data.

†† Mixed indicates that the facility is identified to be in more than one of the facility categories such as private, public, hospital, STD/school/teen clinics.

†† Includes military, WIC clinics, pharmacies, unknown, and missing.

Plot, graph and charts for the variables

Charts, plots and graphs with respect of weights for the **P_UTDHPV_15INT** vaccines as given below.

First histogram is the histogram using Ages at interview in PUF, it is most likely to be evenly distributed across the ages, while the mother's age is clearly left skewed. The income to poverty ratio concaves downwards and then upwards and is also left skewed. About half of the candidates' mother's age is over 45 years old.

First vertical bar-graph is respect to the mother's educational level, 2020 NIS-Teen still over-represented adolescents whose mothers are college graduates (42.3% in survey, 35.2% in population) and under-represented adolescents whose mothers have some college but not a four-year degree (24.1% in survey, 31.2% in population).

With respect to the sex of adolescents, the male was 3%-4% more than the female.

For the Race/Ethnicity, the non-Hispanic white has the highest weighted percentage, followed by the Hispanic, non-Hispanic other+multiple races, the non-Hispanic black has the lowest weighted percentage.

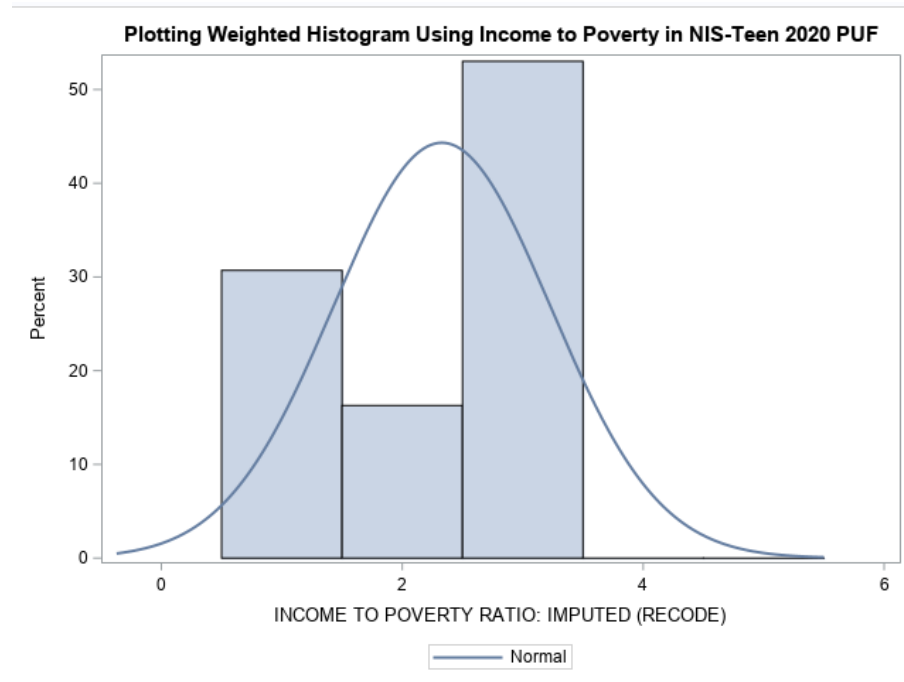

For the mother's marital status, married mother is about twice more than unmarried.

First pie-chart is for the medical insurance, from the chart we can see most of them have private insurance, followed by any Medicaid, other insurance and very few are uninsured.

The well child visit at age 11-12 years, almost all the children had checkups, few had no checkup, and the rest are missing or choose others.

For the vaccine facility type, most of them go to private facility, followed by mixed which means facility is identified to be in more than one of the facility categories such as private, public, hospital, STD/school/teen clinics. Some people go to hospital or public facility. Few choose All STD/school/teen clinics or other facilities. With respect to the census region of adolescent, south group accounts for 38.95%, followed by west 24.15%, the least is northeast group.

III. Result: Part 2 Chi-Square Test

Null hypothesis: The demographic variables are not significantly associated with the P_UTDHPV_15INT vaccine.

Alternative hypothesis: The demographic variables are significantly associated with the P_UTDHPV_15INT vaccine.

Table 2 shows the sample size of the variables, weighted% 95% confidence interval, the chi-square and p-value.

It can be seen that Ages: chi-square =465887.00 PVALUE<0.001, the age groups chi-square =228552.00 PVALUE<0.001, the sex of Adolescent chi-square =62349.07 PVALUE<0.001, Race/Ethnicity chi-square =93321.30 PVALUE<0.001, mother's educational chi-square =126092.00 PVALUE<0.001, mother's marital status chi-square =1396.87 PVALUE<0.001, mother's age chi-square =46847.26 PVALUE<0.001, Income to poverty ratio chi-square =22150.33 PVALUE<0.001, medical chi-square =121735.00 PVALUE<0.001, well child visit at age 11-12years chi-square =777661.00 PVALUE<0.001, census chi-square =167002.00 PVALUE<0.001, and vaccination facility type chi-square =150358.00 PVALUE<0.001.

From the chi-square statistics and p-value, we can see that the demographic variables are significantly associated with the P_UTDHPV_15INT vaccine.

VII. Result: Model Regression Results

Table 6 shows 3 models' test of effect models.

In model 2, it is shown that the unadjusted odds ratio for the age of the adolescent in years is significant (Chi-Square = 29.55, P-value < 0.001), the sex of the adolescent is significant (Chi-Square = 15.56, P-value < 0.001), the race/ethnicity is significant (Chi-Square = 7.56, P-value < 0.001), the mother's educational level is significant (Chi-Square = 10.34, P-value < 0.001), the mother's marital status is not significant (Chi-Square = 10.34, P-value = 0.56), the mother's age is not significant (Chi-Square = 5.76, P-value = 0.003), the income to poverty ratio is not significant (Chi-Square = 4.9, P-value = 0.03), the medical insurance is relatively not significant (Chi-Square = 8.05, P-value = 0.001), the well child visit at age 11-12 years is significant (Chi-Square = 84.35, P-value < 0.001), the census region is significant (Chi-Square = 20.24, P-value < 0.001), and the vaccination facility type is significant (Chi-Square = 7.90, P-value < 0.001).

In model 3, it is shown that the adjusted odds ratio for the age of the adolescent in years is significant (Chi-Square = 10.26, P-value < 0.001), the sex of the adolescent is significant (Chi-Square = 19.66, P-value < 0.001), the race/ethnicity is significant (Chi-Square = 11.34, P-value < 0.001), the mother's educational level is significant (Chi-Square = 9.68, P-value < 0.001), the mother's marital status is not significant (Chi-Square = 0.00, P-value = 0.95), the mother's age is not significant (Chi-Square = 0.82, P-value = 0.44), the income to poverty ratio is not significant (Chi-Square = 3.11, P-value = 0.08), the medical insurance is relatively not significant (Chi-Square = 5.11, P-value = 0.001), the well child visit at age 11-12 years is significant (Chi-Square = 44.48, P-value < 0.001), the census region is significant (Chi-Square = 19.43, P-value < 0.001), and the vaccination facility type is significant (Chi-Square = 5.76, P-value < 0.001).

In model 4, the adjusted odds ratio for the variables that were significant in model 3 which was Age, Sex, Race/Ethnicity, Mother's Educational Level, well child visit at age 11-12 years, census region, vaccination facility.

The adjusted odds ratio for the race/ethnicity is significant (Chi-Square = 14.14, P-value = 0.001), the sex of the adolescent is significant (Chi-Square = 20.03, P-value < 0.001), the mother's educational level is significant (Chi-Square = 8.46, P-value < 0.001), the age of the adolescent in years is significant (Chi-Square = 10.48, P-value < 0.001), the well child visit at age 11-12 years is significant (Chi-Square = 47.12, P-value = 0.001), the census region is significant (Chi-Square = 20.92, P-value = 0.001), the vaccination facility type is significant (Chi-Square = 5.98, P-value = 0.001).

VIII. Conclusion

This project was designed to do the analysis of (NIS-Teen) 2020 data. Among all the vaccines types, my project is solely P_UTDHPV_15INT. 20163 people participated the survey. In my analysis, I conducted descriptive statistics analysis were for all the variables in order to give you a brief idea about how the data set constructed. Then the analysis gives you weighted and unweighted estimates, point estimates and corresponding 95% confidence intervals. What's more, four models were fitted for the data which included weighted estimates, adjusted and unadjusted odds ratios.

For the regression model, the wald chi-square was used to determine if the variables were significant. In model 2 which is an unadjusted odds ratio, Age, Sex, Race/Ethnicity, mother's educational level, Well Child Visit at Age 11-12 Years, Census Region, Vaccination Facility Type were all significant. Meanwhile, mother's marital status, Mother's Age, Medical Insurance and income to poverty ratio were not significant.

With respect to model 3 which is an adjusted odds ratio, the result is same as model 2. Among all the variables, Age, Sex, Race/Ethnicity, mother's educational level, Well Child Visit at Age 11-

12 Years, Census Region, Vaccination Facility Type were all significant. Meanwhile, mother's marital status, Mother's Age, Medical Insurance and income to poverty ratio were not significant.

Model 4 is also an adjusted odds ratio using only the variables significant in model 3, it was confirmed that all the variables that were significant in model 3 were also significant in model 4.
